

# 13 Physics AS 91525 Demonstrate Understanding of Modern Physics

## BIG Ideas to Remember

Concept: Nuclear Reactions	<ol style="list-style-type: none"><li>1. Particles released during spontaneous nuclear decay include alpha (<math>{}^4\text{He}_2</math>), beta (<math>\text{e}^{-}</math>), protons (<math>{}^1\text{p}_1</math>), neutrons (<math>{}^1\text{n}_0</math>) and pure energy gamma too.</li><li>2. Nuclear decay processes may be spontaneous, single nucleus decomposition, OR induced artificial decay caused by collision of a smaller and larger nucleus.</li><li>3. In all nuclear reactions Conservation of mass number, atomic number, momentum and mass-energy occurs</li><li>4. <math>E = \Delta m c^2</math> where <math>c = 3 \times 10^8 \text{ ms}^{-1}</math> (speed of light)</li><li>5. The electron-volt is a measure of energy (<math>1.6 \times 10^{-19}\text{J}</math>) since <math>W = \Delta V.Q</math></li></ol>
Concept: Nuclear Stability	<ol style="list-style-type: none"><li>1. The nucleus' mass is less than the sum of the nucleons' mass.</li><li>2. Mass of nucleus includes the energy of the nucleus. Total mass = mass of nucleons + energy of nucleus</li><li>3. Mass of each nucleon is less when it is inside the nucleus than when it is free.</li><li>4. <b>Mass deficit</b> is the reduction of mass when the nucleons form the nucleus.</li><li>5. <b>Binding energy</b> is the amount of energy which must be supplied to make up mass deficit when the nucleus is broken up,</li></ol>
Concept: Binding Energy; Fission and Fusion	<ol style="list-style-type: none"><li>1. <b>Binding energy per nucleon</b> shows the strength of the nuclear glue.</li><li>2. Increased binding energy per nucleon means increased stability of the nucleus (<math>\text{Fe}^{56}_{26}</math> is most stable nucleus).</li><li>3. Nuclei with the lowest mass per nucleon have the biggest binding energy and their nucleons have the lowest energy.</li><li>4. Fission occurs when a large nucleus is split into smaller nuclei and a large amount of gamma radiation energy is released.</li><li>5. Fusion occurs when two light nuclei join together and a large amount of gamma radiation energy is released.</li></ol>
Concept: Electrons in the Atom and Energy Levels.	<ol style="list-style-type: none"><li>1. Light given out by excited low-pressure gases can be diffracted to form emission spectrums of converging lines.</li><li>2. An absorption spectrum is caused by white light shing on a gas and causes dark spectral lines that converge.</li><li>3. The Hydrogen atom's spectral lines represent transitions between energy levels that are related by <math>1/\lambda = R (1/S^2 - 1/L^2)</math> where S is the series number and L is the line number.</li><li>4. The series are Lyman            u.v.            S = 1 Balmer           visible        S = 2 Paschen        infra-red      S = 3 Brackett       infra-red      S = 4 Pfund           infra-red      S = 5</li><li>5. The limiting wavelength represents the energy to remove electrons from atoms (ionise the atom)</li></ol>
Concept: Bohr's Model of the Atom	<ol style="list-style-type: none"><li>1. <math>E = hf</math> and <math>\lambda = c / f</math> (<math>c = f\lambda</math>)</li><li>2. <math>E = hcR/S^2 - hcR / L^2</math> and represents the energy difference between two energy levels</li><li>3. Electrons in the Hydrogen atom can only exist within energy levels given by <math>E = - hcR/ n^2</math></li><li>4. Electrons with zero energy will leave nucleus (ionisation occurs)</li><li>5. An atom's energy levels can be described by the Principal Quantum Number, <math>n = 1,2,3,\dots,</math></li></ol>

Explaining the Emission Spectrum	<ol style="list-style-type: none"> <li>1. Each series of lines in the Hydrogen atom's spectrum represents the energy released when electrons "fall" from a higher energy level to a lower energy level.</li> <li>2. The series are called Lyman, Balmer, Paschen, Brackett and Pfund</li> <li>3. The smallest energy release for any of the series is significantly greater than the largest energy drop of the next series.</li> <li>4. The energy released is directly proportional to the frequency of the emitted photon</li> <li>5. Photons are 'packets of light energy' with discrete, measurable frequency and energy: <math>E = hf</math></li> </ol>
The Photo-electric Effect	<ol style="list-style-type: none"> <li>1. The Photo-electric Effect is the emission of electrons from zinc or sodium metal's surface when light shines on the surface of the metal.</li> <li>2. Brighter light causes more electrons to be released but does not change the energy of the electrons emitted.</li> <li>3. Ultra-violet light causes instantaneous release of electrons.</li> <li>4. Higher frequency of incident light releases emitted electrons with greater energy.</li> <li>5. <math>E = hf</math> for photons, so light shining onto the metal surface can be thought of as a continuous stream of energy particles and this energy is transferred to the electrons in the surface of the metal.</li> </ol>
The Photo-Electric Effect and Wave-Particle Duality	<ol style="list-style-type: none"> <li>1. If the energy transferred from the photons is just enough to release electrons from the surface (just equal to the Work function) then electrons will be released.</li> <li>2. If the energy of the photons is more than is needed to release the electron. Then the electron will be emitted with kinetic energy, <math>E_k</math>.</li> <li>3. Brighter light means more photons, so more electrons will be emitted by the metal's surface. <math>E_k = hf - \phi</math> where <math>E_k</math> is kinetic energy, <math>hf</math> is photon's energy, <math>\phi</math> is Work function</li> <li>4. Light of a particular frequency can be modelled as an electro-magnetic wave of a particular, very small wavelength, and this wave travels at a very high speed, <math>c</math>.</li> <li>5. Light can also be modelled as photons that have both wave and particle properties (wave – packets) and the photon has a measurable, fixed value of energy (<math>E = hf</math>, &amp; <math>E = hc/\lambda</math>)</li> </ol>

Photon energy

$$E = hf$$

explains the experiment and shows that light behaves like particles.

Einstein's General and Special Theory of Relativity	<ol style="list-style-type: none"> <li>1. After light has left a source, its motion cannot be influenced by the motion of the source; so the speed of light in a vacuum is independent of the motion of the source.</li> <li>2. The rate of time apparent on a moving object seems to be slower than the rate of time in another stationary situation, as seen by a person in this stationary situation.</li> <li>3. The length of a ruler that is moving at a high speed appears to be shorter than it is when it is stationary, as seen by a stationary person.</li> <li>4. The mass of an object seems to increase as the mass approaches the speed of light, as seen by a stationary observer.</li> <li>5. The Lorentz Transformation describes the relative changes in time, length and mass.</li> </ol>
Qualitative Treatment of Quarks and Leptons	<ol style="list-style-type: none"> <li>1. The Standard Model tries to explain what the world is and what holds it together.</li> <li>2. All the known matter particles are composites of quarks and leptons, and they interact by exchanging force carrier particles</li> <li>3. Physicists have discovered that <b>protons</b> and <b>neutrons</b> are composed of even smaller particles called <b>quarks</b>.</li> <li>4. The Standard Model of the Atom explains that the atom is made up of Fermions including only 6 Quarks and 6 Leptons (the electron is one of the Leptons).</li> <li>5. Also there are five Force Carrier "Bosons" including the Higgs Boson, the gluon and the Photon</li> </ol>

## Elementary Particles
